# **Solutions 5**

# Exercise 5.1.

- 1. First, note that *G* has rank *k*, because of the triangular minor it contains. Moreover, the rows of *G*, when interpreted as polynomials, represent  $g(x), xg(x), \ldots, x^{k-1}g(x)$  which form a basis for the ideal in  $\mathbb{F}_2[x]/(x^n 1)$  generated by g(x), i.e., the code C.
- 2. For any codeword  $c(x) = \sum_{i=0}^{n-1} c_i x^i$ , we can write c(x) = f(x)g(x) for some polynomial f(x) of degree less than n k. Then

$$c(x)h(x) = f(x)g(x)h(x) = 0 \pmod{x^n - 1}.$$

The coefficient of  $x_j$  in this product is

$$\sum_{i=0}^{n-1} c_i h_{j-i} = 0, \ j = 0, \dots, n-1,$$
(1)

where the subscripts are taken modulo n. This gives us n check equations satisfied by the codewords of C. Let

$$H := \begin{pmatrix} h_k & h_{k-1} & \cdots & h_0 & 0 & 0 & \cdots & 0\\ 0 & h_k & h_{k-1} & \cdots & h_0 & 0 & \cdots & 0\\ 0 & 0 & \ddots & \ddots & \ddots & \ddots & \ddots & 0\\ 0 & 0 & 0 & \cdots & h_k & h_{k-1} & \cdots & h_0 \end{pmatrix}$$

Clearly, from (1), if  $c \in C$  then  $Hc^{\top} = 0$ . Conversely, note that H has rank n - k because of the triangular minor it contains, so that the codition  $Hc^{\top} = 0$  is a sufficient condition for c to be in C. Thus H is a parity check matrix for C.

3. From  $g(x)h(x) = x^7 - 1$ , we get that  $h(x) = x^4 + x^2 + x + 1$ , and thus by the result in the preceding section, we will have

$$G = \begin{pmatrix} 1 & 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 & 1 \end{pmatrix},$$
$$H = \begin{pmatrix} 1 & 0 & 1 & 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 & 1 & 1 \end{pmatrix}.$$

This code is equivalent to a [7, 4, 3] Hamming code (i.e., it is the Hamming code up to a permutation of the codeword coordinates).

#### Exercise 5.2.

- 1. As *n* is relatively prime to the field size,  $x^n 1$  has no duplicate factors and thus gcd(g(x), h(x)) = 1. Now we can apply Bezout's identity and conclude that there exist a(x) and b(x) such that a(x)g(x) + b(x)h(x) = gcd(g(x), h(x)) = 1.
- 2. We have that c(x) := a(x)g(x) = 1 b(x)h(x). Thus, for every codeword f(x), we will have

$$c(x)f(x) = f(x) - b(x)f(x)h(x) = f(x).$$

In particular, letting f(x) = c(x), we get that  $c(x)^2 = c(x) \mod x^n - 1$ . Also, since we know that every codeword w(x) of C can be written as a multiple of c(x), namely, w(x)c(x), it follows that c(x) generates C.

For the uniqueness, assume that there is a codeword c'(x) such that for all codewords f(x) of C, f(x)c'(x) = f(x). Now let f(x) = c(x); thus, c(x)c'(x) = c(x). Similarly, c having the same property implies that c'(x)c(x) = c'(x), which gives c(x) = c'(x).

### Exercise 5.3.

- 1. If  $c \in C_1 \cap C_2$  and c' is any cyclic shift of c, we must have that  $c \in C_1$  thus  $c' \in C_1$  and similarly,  $c' \in C_2$ , which means  $c' \in C_1 \cap C_2$  and that  $C_1 \cap C_2$  is cyclic. For the generator polynomial, let  $g(x) = \text{LCM}(g_1(x), g_2(x))$ ; the least common multiple of  $g_1(x)$  and  $g_2(x)$ . Every codeword in the intersection is divisible by both  $g_1(x)$  and  $g_2(x)$ , and thus, by g(x). Conversely, every multiple of g(x) is both a multiple of  $g_1(x)$  and  $g_2(x)$  and must belongs to both codes. This means that  $C_1 \cap C_2$  is generated by g(x).
- 2. Let  $c := c_1 + c_2 \in C_1 + C_2$ , where  $c_1 \in C_1$  and  $c_2 \in C_2$ , and consider a cyclic shift of c, denoted by c', and corresponding cyclic shifts of  $c_1$  and  $c_2$  denoted by  $c'_1$  and  $c'_2$ , respectively. We must have that  $c' = c'_1 + c'_2$ , and  $c'_1$  (resp.,  $c'_2$ ) must belong to  $C_1$  (resp.,  $C_2$ ) by the properties of  $C_1$  and  $C_2$ . This means that  $c' \in C_1 + C_2$  and thus  $C_1 + C_2$  is cyclic. Now consider the polynomial  $g(x) = \gcd(g_1(x), g_2(x))$ . First we observe that every multiple of  $g_1(x)$  or  $g_2(x)$  is a multiple of g(x) as well, which means that the code generated by g(x) contains both  $C_1$  and  $C_2$  and hence  $C_1 + C_2$ . Now, by Bezout's identity,

$$g(x) = a(x)g_1(x) + b(x)g_2(x) \mod x^n - 1$$

for some a(x), b(x), so that every multiple of g(x) (e.g., g(x)u(x)) can be written as the summation  $a(x)u(x)g_1(x) + b(x)u(x)g_2(x)$  which is a multiple of  $g_1(x)$  plus a multiple of  $g_2(x)$ . Thus the code generated by g(x) is contained in  $C_1 + C_2$ . We conclude that  $C_1 + C_2$  is the cyclic code generated by g(x).

## Exercise 5.4.

1. Suppose that  $\lambda$  is a nonzero linear form on  $\mathbb{F}_2^k$ . Its image is nontrivial, so that its kernel has dimension k - 1; this means that  $\lambda$  vanishes on exactly half the points of  $\mathbb{F}_2^k$ . Thus the solution spaces of  $\lambda(x) = 0$  and  $\lambda(x) = 1$  have equal size.

- 2. By the definition of the  $\epsilon$ -biased set, in each codeword of the evaluation code the number of zeros and ones differ by at most  $\epsilon |S|$ . As the length of the code of |S|, each codeword will have weight (thus, the code will have minimum distance) at least  $(1-\epsilon)|S|/2$ . In particular, the left kernel of a generator matrix of the code whose columns form the set *S* must be trivial, which means that the dimension of the code is *k*.
- 3. As the all-one word is a codeword and the code is linear, the weight distribution of the code is symmetric; i.e., there is a codeword of weight *i* in the code iff there is one of weight n i. Now let G' be the generator matrix G with its first row removed and S be the set of its n columns. Thus, G' is a generator matrix of a subcode of C that does not contain the all-one word. We know that for each nonzero  $x \in \mathbb{F}_2^{k-1}$ , the weight of y := xG' is in the range [d, n d]. Let  $n_0$  and  $n_1$  be the number of zeros and ones in y. Thus we know that  $n_0 + n_1 = n$  and  $n_0, n_1 \in [d, n d]$ , which means  $|n_0 n_1| \leq n 2d = (1 2d/n)|S|$ . Note that the choices of x are in one-to-one correspondence with nonzero elements of  $(\mathbb{F}_2^{k-1})^*$  and the outcomes y are in one-to-one state the set S is  $\epsilon$ -biased, for  $\epsilon = 1 2d/n$ .
